

Netflix stores all kinds of data across its Cassandra DB instances, including all user-collected event metrics.

As user data began to increase, there needed to be a more efficient way to manage data storage. Netflix Redesigned data storage architecture with two main goals in mind:

- Smaller Storage Footprint.
- Consistent Read/Write Performance as viewing per member grows.

The solution to the large data problem was to compress the old rows. Data were divided into two types:

- Live Viewing History (LiveVH): Small number of recent viewing records with frequent updates. The data is stored in uncompressed form.
- Compressed Viewing History (CompressedVH): A large number of older viewing records with rare updates. The data is compressed to reduce the storage footprint. Compressed viewing history is stored in a single column per row key.

*Compressed Viewing History*
